Many government documents contain sensitive information that must be identified and protected before the documents can be released to the public. While manually reviewing such documents for sensitive information it can be important to determine contextual information about specific entities that are mentioned in the documents and whether the information that is discussed about these entities is already in the public domain. In this project, you will develop a system that can automatically identify external information about specific entities from publicly available knowledge graphs (e.g. Wikidata or DBpedia). The system should be able to assist human sensitivity reviewers by identifying entities that are referenced by different names in the collection (based on the entity's attributes) and whether personal information about named entities is in the public domain.

You will work with named entity recognition tools (e.g. spacy https://spacy.io/) along with entity linking tool such as ReFinED (https://github.com/amazon-research/ReFinED) or DBpedia Spotlight (https://www.dbpedia.org/resources/spotlight/). A graph databases such as Neo4j (https://neo4j.com/) will likely also be used to dynamically build a definitive view of the entities within the document collection.

## Summary of what was agreed last week?

- Get entities to be recognised and displayed in a different colour
- Wireframes
- User stories
- Project summary in my own words

## Progress made in the past week

- Documents display on corresponding page, entities show in different colours
- Database is fully functional
- Wireframes, user stories and project summary completed
- Documents currently uploaded as .txt but will be changed for .html

## • Main questions for discussion

- Possible technologies to overlay entity info over document
- Whether documents need to be redisplayed in the formatting they were uploaded in
- How important is a sensitivity detection model as opposed to assisting a reviewer

## · Feedback from meeting
